

NETWORK DEVICE TEST

1) Explain Behaviours of hub device?

Hub is used to connect multiple network devices. It is a single layer device, It is a Broadcast device.

Hub is Act as one way communication.

If you have three PC means. You can Interconnect PC and share data using Hub. But Hub can share the data broadcast only. So there may network traffic happens which makes our network slow.

Drawbacks in hub: • Broadcast - one way communication
• Collision

2) Explain Behaviours of Switch device?

A Switch is a Advanced version of Hub.

Switch is Build for reduce network traffic and slowness.

Switch can Act as Broadcast & Unicast. The Special different from hub is Switch has Mac table.

which holds the Mac address of PCs. It can store the Address temporarily upto 5 minutes.

So that It can easily Identify the PC and communicate in Unicast. So that we can avoid network traffic.

3) Explain Behaviours of Router device?

Router is advanced network device which uses Routing function. Forward one packet data from one network to another network is called routing. Router has Routing table which contains IP address of all connected networks. So when the packet send from one network router identifies the destination network by using Routing table and ~~then~~ send the data to respective network in a unicast way. So we can avoid Broadcasting.
